## Mathematics 243, section 1 – Algebraic Structures Solutions for Exam 2, November 1, 2006

I. Think of  $\mathbb{R}^2$  (the set of ordered pairs of real numbers) as the ordinary Cartesian coordinate plane. Let R be the relation on  $\mathbb{R}^2$  defined by

$$(x_1, y_1)R(x_2, y_2) \Leftrightarrow 3x_1 + y_1 = 3x_2 + y_2$$

A) (15) Show that R is an equivalence relation on  $\mathbb{R}^2$ .

Solution: R is reflexive because for all points  $(x,y) \in \mathbf{R}^2$ , 3x + y = 3x + y, hence (x,y)R(x,y).

R is symmetric because if  $(x_1, y_1)R(x_2, y_2)$ , then  $3x_1 + y_1 = 3x_2 + y_2$ , so  $3x_2 + y_2 = 3x_1 + y_1$ , and  $(x_1, y_1)R(x_2, y_2)$ .

R is transitive because if  $(x_1, y_1)R(x_2, y_2)$  and  $(x_2, y_2)R(x_3, y_3)$ , then  $3x_1 + y_1 = 3x_2 + y_2$  and  $3x_2 + y_2 = 3x_3 + y_3$ , so  $3x_1 + y_1 = 3x_3 + y_3$ .

B) (5) Draw a picture of the equivalence class [(2,3)] for this relation.

Solution: The equivalence class of the point (2,3) is the set of all points (x,y) such that (x,y)R(2,3), so 3x + y = 9. This is the line y = -3x + 9 with slope -3 and y-axis intercept at (0,9).

II. (20) Prove by mathematical induction: For all  $n \geq 1$ ,

(1) 
$$1^3 + 3^3 + 5^3 + \dots + (2n-1)^3 = n^2(2n^2 - 1).$$

Solution: The base case is n = 1. For n = 1, the left side of the formula (1) is  $1^3 = 1$ , and the right side is  $1^2(2 \cdot 1 - 1)$  so the formula is true for n = 1.

For the induction step assume that (1) is true for n = k. Then with n = k + 1, by the induction hypothesis and the binomial theorem we have

$$1^{3} + 3^{3} + 5^{3} + \dots + (2k-1)^{3} + (2(k+1)-1)^{3} = k^{2}(2k^{2}-1) + (2(k+1)-1)^{3}$$
$$= 2k^{4} - k^{2} + (2k+1)^{3}$$
$$= 2k^{4} - k^{2} + 8k^{3} + 12k^{2} + 6k + 1$$
$$= 2k^{4} + 8k^{3} + 11k^{2} + 6k + 1$$

On the other hand, we are trying to show that this is the same as the right side of (1) with n = k + 1, namely,

$$(k+1)^{2}(2(k+1)^{2}-1) = (k^{2}+2k+1)(2k^{2}+4k+1)$$
$$= 2k^{4}+8k^{3}+11k^{2}+6k+1$$

Since the two sides of (1) agree for n = k + 1, the formula is true for all  $n \ge 1$  by the Principle of Mathematical Induction.

III.

A) (15) Give the precise statement of the division algorithm in **Z**, and prove the existence part.

Solution: The statement is that for all integers a and b > 0, there exist unique integers q, r such that

(2) 
$$a = qb + r$$
 and  $0 \le r < b$ .

We must show that q, r as in (2) exist. So consider the set of integers

$$S = \{a - qb : q \in \mathbf{Z}\}\$$

If  $0 \in S$ , then a = qb + 0 for some q and both parts of (2) are satisfied. So this case is done, and for the rest of the proof we will assume  $0 \neq S$ .

If a is positive then S contains positive elements such as a - 0q = a. If a is negative, we will still have positive elements in S by taking q negative with sufficiently large absolute value. Hence  $S \cap \mathbf{N} \neq \emptyset$ . The Well-Ordering Principle implies that  $S \cap \mathbf{N}$  has a smallest element. Call this smallest positive element r. Then we have r = a - qb for some  $q \in \mathbf{Z}$  and the first statement in (2) is true since a = qb + r. The remainder of the proof (cue laugh-track!) is to show that 0 < r < b. (Note that we have ruled out the case r = 0 above.) If  $r \geq b$ , then we claim that a contradiction results. This is because

$$r \ge b \Rightarrow a - qb = r \ge b$$
  
  $\Rightarrow a - (q+1)b = r - b \ge 0$ 

The integer a - (q+1)b is also in the set S by definition. Hence either  $0 \in S$  which is ruled out above, or else r-b>0 is in S. But r-b< r since b>0. This is a contradiction to the way we found r (it was supposed to be the smallest positive element in S). Hence if  $r \neq 0$ , then 0 < r < b (which is another way of saying  $0 \le r < b$ ).

B) (5) Let a, b, c, q, r be integers. Show that if c|a, c|b, and a = qb + r, then c|r.

Solution: Since c|a and c|b, there exist integers m, n such that a = mc and b = nc. Then

$$mc = qnc + r \Rightarrow r = c(m - qn)$$

which shows that c|r.

C) (15) Use the Euclidean algorithm to find the integer  $d = \gcd(576, 99)$  and express d in the form  $d = m \cdot 576 + n \cdot 99$  for some integers m, n.

Solution: We first carry out the divisions:

$$576 = 5 \cdot 99 + 81$$
$$99 = 1 \cdot 81 + 18$$
$$81 = 4 \cdot 18 + 9$$
$$18 = 2 \cdot 9 + 0$$

The last non-zero remainder is  $9 = \gcd(576, 99)$ . (Note that 5 + 7 + 6 = 18 = 9 + 9 so we could tell both numbers are divisible by 9 by the "sum of digits" test.) Then

which shows that

$$5 \cdot 576 + (-29) \cdot 99 = 9 = \gcd(576, 99).$$

IV.

A) (10) Find a solution x of the congruence  $31x \equiv 2 \mod 64$  with  $0 \le x < 63$ .

Solution: Since gcd(31,64) = 1, there will be a unique solution and we want a multiplicative inverse of 31 mod 64 to find it.

$$64 = 2 \cdot 31 + 2$$
$$31 = 15 \cdot 2 + 1$$

Hence

So  $[31] = [31]^{-1}$  in  $\mathbb{Z}_{64}$ , since  $(-15) \cdot 64 + 31 \cdot 31 = 1$ . We obtain  $x \equiv 2 \cdot 31 \mod 64$  so x = 62 is one solution. (The others are the integers  $x = 62 + 64\ell$  for all  $\ell \in \mathbb{Z}$ .)

B) (10) For which  $[b] \in \mathbf{Z}_{16}$  do solutions  $[x] \in \mathbf{Z}_{16}$  of the equation [12][x] = [b] exist? Explain how you can tell.

Solution: By problem 35 from section 2.5, in order for  $ax \equiv b \mod n$  to have a solution, b must be divisible by  $\gcd(a,n)$ . Here  $\gcd(12,16)=4$ , so there are solutions when b=0,4,8,12. (For instance, with b=0 we can take x=0; with b=4 we can take x=3; with b=8 we can take x=2; with b=12 we can take x=1. There are other solutions too in each case, which can be found by the process in problem 36 from section 2.5.)
